Outline

Outline

Equivalence Relation

A relation over a set S is said to be an equivalence relation over S iff it is symmertric, reflexive, and transitive over S.

- **reflexive**: $x \equiv x$ for each $x \in S$.
- **symmetric**: for $x, y \in S$, if $x \equiv y$, then $y \equiv x$.
- **transitive**: for x, y, z, if $x \equiv y$ and $y \equiv z$, then $x \equiv z$.

Equivalence Relation

A relation over a set S is said to be an equivalence relation over S iff it is symmertric, reflexive, and transitive over S.

- **reflexive**: $x \equiv x$ for each $x \in S$.
- **symmetric**: for $x, y \in S$, if $x \equiv y$, then $y \equiv x$.
- **transitive**: for x, y, z, if $x \equiv y$ and $y \equiv z$, then $x \equiv z$.

Example

Given $0 \equiv 4$, $3 \equiv 1$, $6 \equiv 10$, $8 \equiv 9$, $7 \equiv 4$, $6 \equiv 8$, $3 \equiv 5$, $2 \equiv 11$, $11 \equiv 0$.

Equivalence Relation

A relation over a set S is said to be an equivalence relation over S iff it is symmertric, reflexive, and transitive over S.

- **reflexive**: $x \equiv x$ for each $x \in S$.
- **symmetric**: for $x, y \in S$, if $x \equiv y$, then $y \equiv x$.
- **transitive**: for x, y, z, if $x \equiv y$ and $y \equiv z$, then $x \equiv z$.

Example

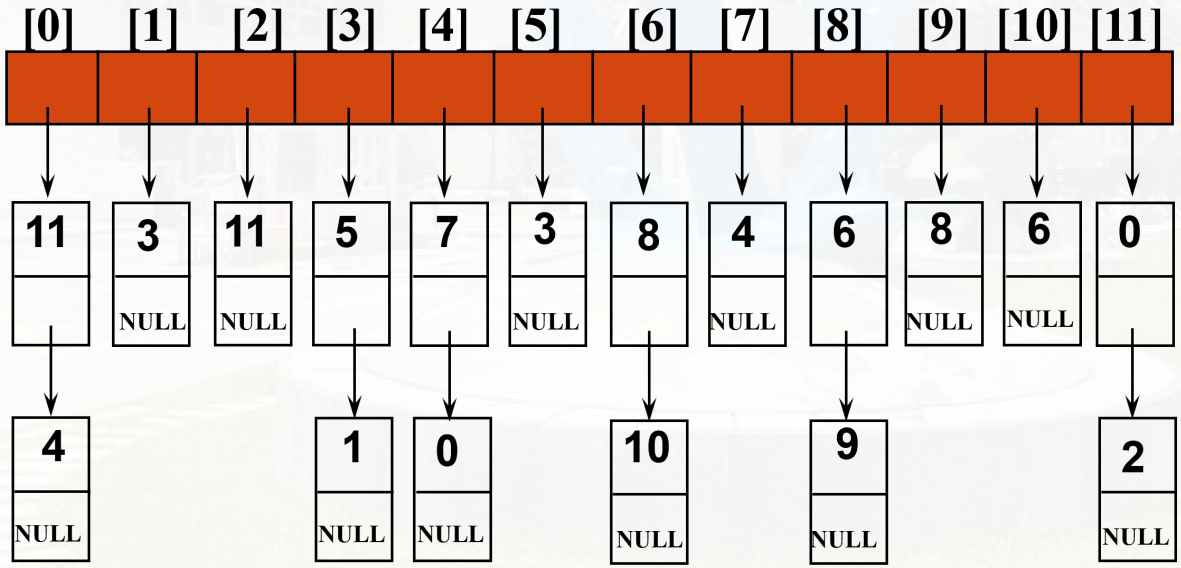
Given $0 \equiv 4$, $3 \equiv 1$, $6 \equiv 10$, $8 \equiv 9$, $7 \equiv 4$, $6 \equiv 8$, $3 \equiv 5$, $2 \equiv 11$, $11 \equiv 0$.
We have three equivalent classes:

$$\{0, 2, 4, 7, 11\}, \{1, 3, 5\}, \{6, 8, 9, 10\}.$$

Lists after Giving Pairs as the Input

$0 \equiv 4, 3 \equiv 1, 6 \equiv 10, 8 \equiv 9, 7 \equiv 4,$
$6 \equiv 8, 3 \equiv 5, 2 \equiv 11, 11 \equiv 0.$

```
typedef struct node *nodePointer;
typedef struct node {
    int data;
    nodePointer link;
};
```



The Equivalence Algorithm (Full Code HERE)

`seq[n]`: hold the head nodes of the n lists; `out[n]`: whether the object i has been printed.

```
void equivalence() {
    initialize seq[i] = NULL, out[i] to true for each i
    while (there are more pairs) {
        read the next pair <i,j>;
        put j on the seq[i] list;
        put i on the seq[j] list;
    }
    for (i=0; i<n; i++) { // the 2nd phase
        if (out[i]) {
            out[i] = false;
            output this equivalence class;
        }
    }
}
```

The Equivalence Algorithm (second phase in detail)

```
for (i=0; i<n; i++) { // the 2nd phase
    if (out[i]) {
        printf("\nNew Classes: %d", i);
        out[i] = false;
        x = seq[i]; top = NULL; // initial stack
        while (1) { // find the rest of the class
            while (x) { // process the list
                j = x->data;
                if (out[j]) {
                    printf("%d", j);  out[j] = false;
                    y = x->link; x->link = top; top = x; x = y;
                } else x = x->link;
            }
            if (!top) break;
            x = seq[top->data]; top = top->link; // pop the stack
        }
    }
}
```

Outline

Issues for Previous Representation

- When we performed matrix operations such as $+$, $-$, or $*$, the number of **nonzero terms** varied.
- The sequential representation of sparse matrices suffered from the same inadequacies as the similar representation of polynomials.

Solution:

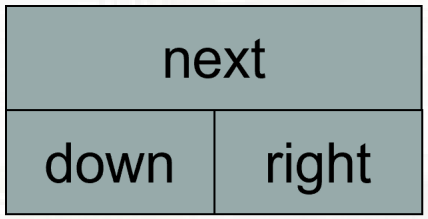
- Linked list representation for sparse matrices.

Issues for Previous Representation

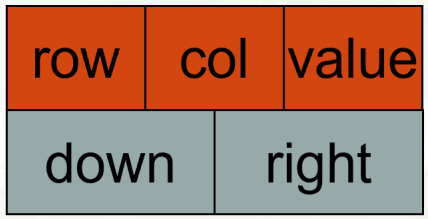
- When we performed matrix operations such as $+$, $-$, or $*$, the number of **nonzero terms** varied.
- The sequential representation of sparse matrices suffered from the same inadequacies as the similar representation of polynomials.

Solution:

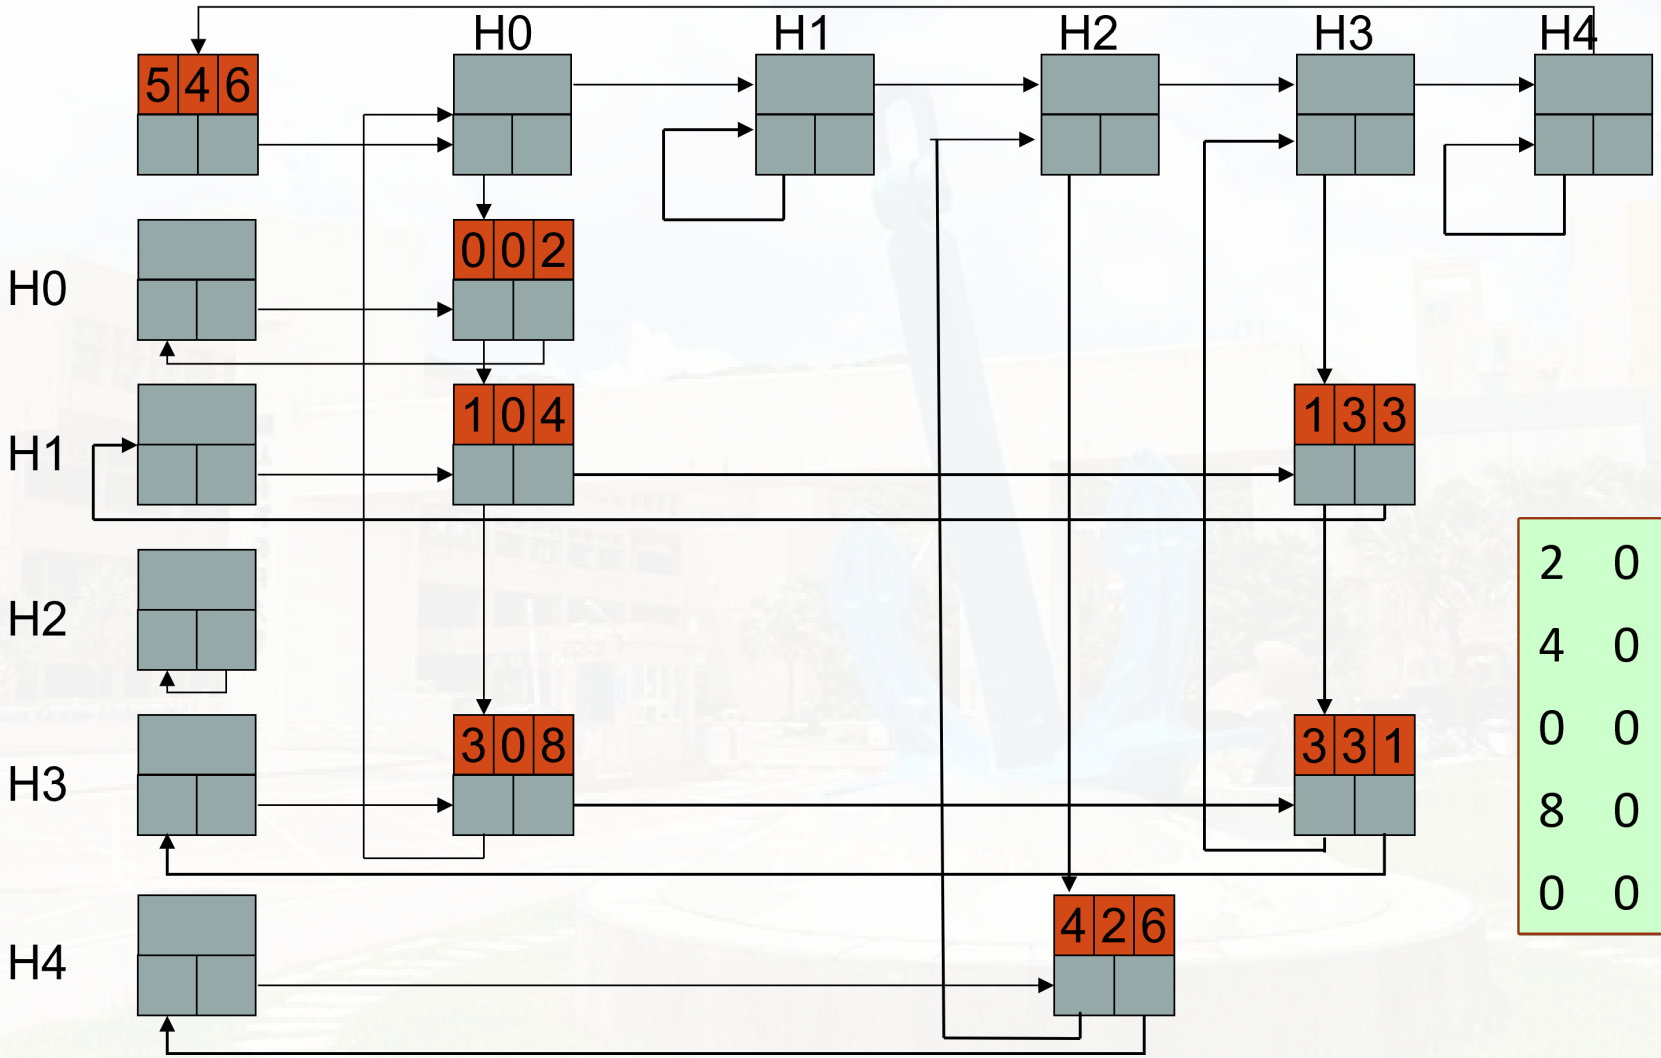
- Linked list representation for sparse matrices.
- Two types of nodes in the representation: header nodes and element nodes.



header node



element node



2	0	0	0
4	0	0	3
0	0	0	0
8	0	0	1
0	0	6	0

Sparse Matrix Representation

- We represent each column (row) of a sparse matrix as a circularly linked list with a header node.
- The header node for row i is also the header node for column i. The number of header nodes is $\max\{\text{numRows}, \text{numCols}\}$.
- Each element node is simultaneously linked into two lists: a row list, and a column list.
- Each head node is belonged to three lists: a row list, a column list, and a header node list.

Outline

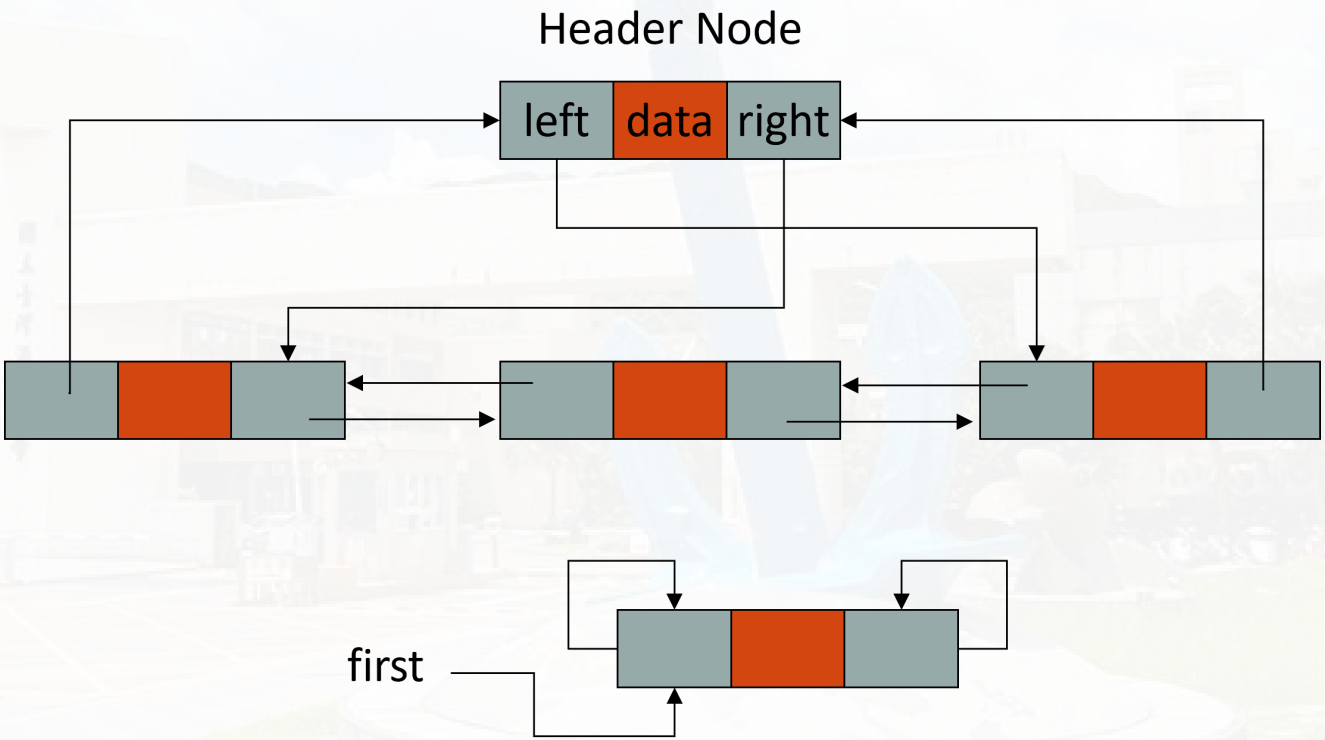
Issues for Singly Linked Lists

- The only way to find the node that precedes some node p is to start at the beginning of the list.
- Sometimes it is necessary to move in either direction.

Doubly linked lists:

```
typedef struct node *nodePointer;
typedef struct node {
    nodePointer llink;
    element data;
    nodePointer rlink;
};
```

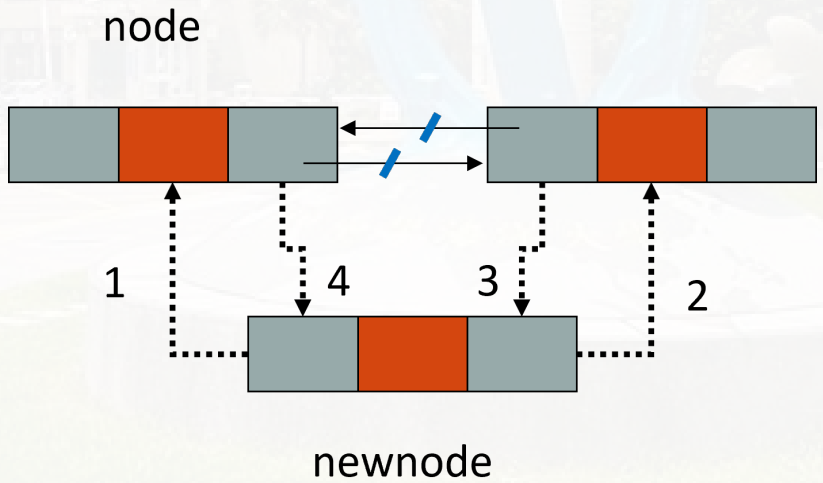
```
ptr = ptr->llink->rlink = ptr->rlink->llink
```



Empty doubly linked circular list with header node

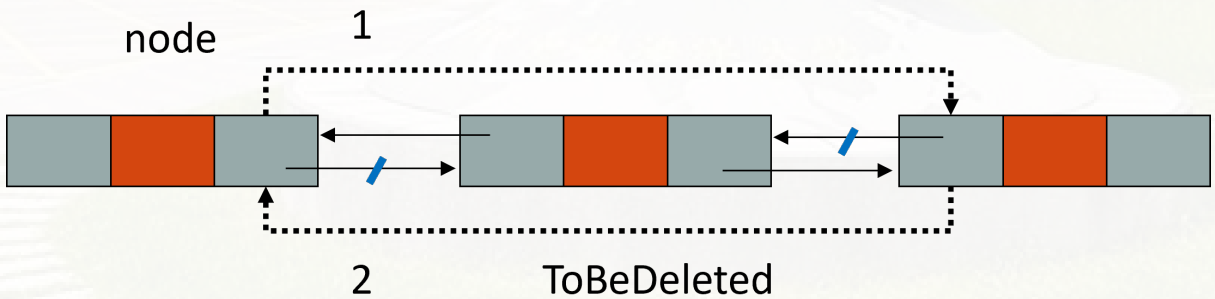
Insertion into a doubly linked circular List

```
void d_LCL_insert(nodePointer node, nodePointer newnode) {
/* insert newnode to the right of node */
    newnode->llink = node;           // 1
    newnode->rlink = node->rlink;    // 2
    node->rlink->llink = newnode;    // 3
    node->rlink = newnode;           // 4
}
```



Deletion from a doubly linked circular list

```
void d_LCL_delete(nodePointer node, nodePointer ToBeDeleted) {
/* delete from the doubly linked list */
    if (node == ToBeDeleted)
        printf("Deletion of header node not permitted.\n");
    else {
        ToBeDeleted->llink->rlink = ToBeDeleted->rlink;  // 1
        ToBeDeleted->rlink->llink = ToBeDeleted->llink;  // 2
        free(ToBeDeleted);
    }
}
```



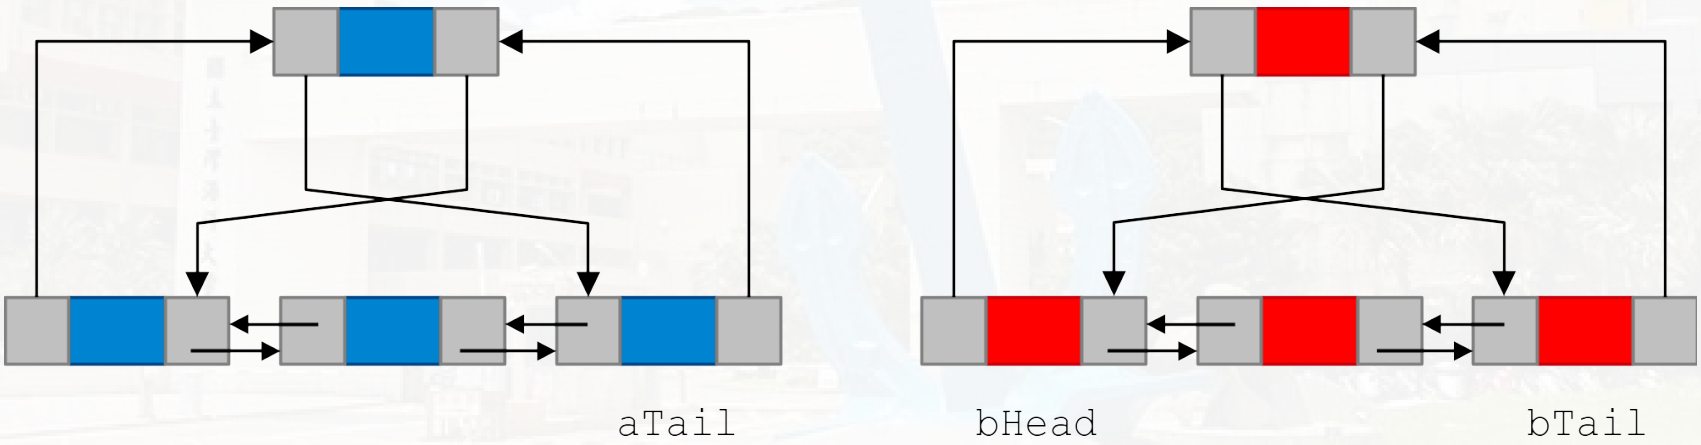
Benefit of using the node "ToBeDeleted"

- The node `ToBeDeleted` can be used as a guide for its right node and left node to update the links.
- No additional temporary nodePointer is required.

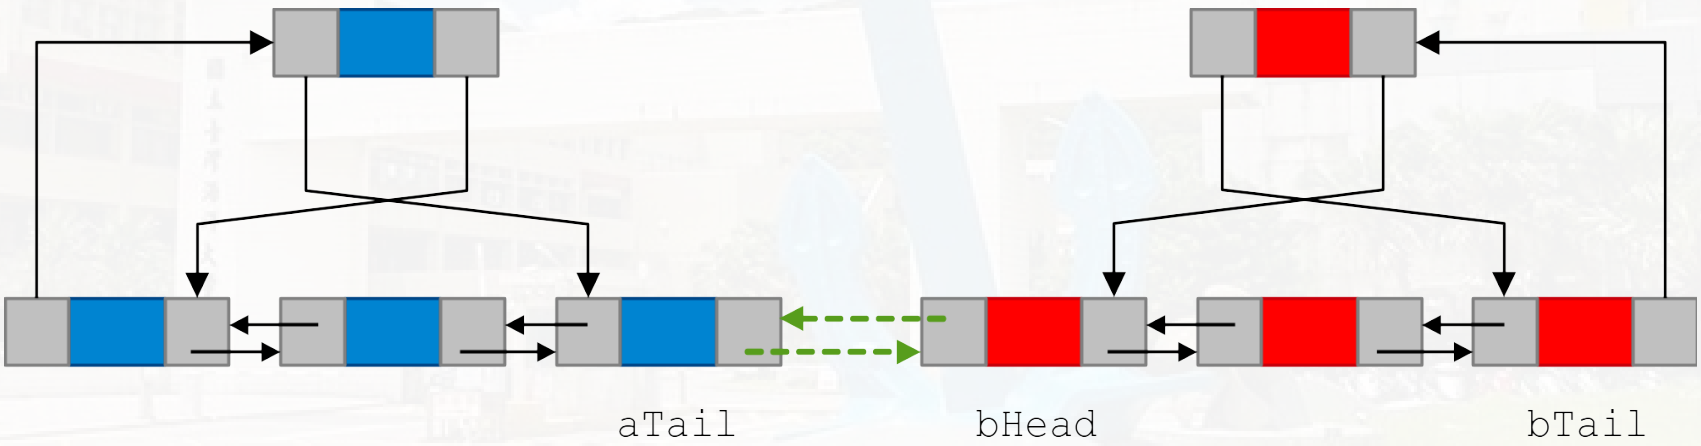
Benefit of using doubly linked circular list

- Concatenation of two lists: $O(1)$ time.
  - Using the header node.
- Inversion of a list: $O(1)$ time (consider `llink` as `rlink` and vice versa).

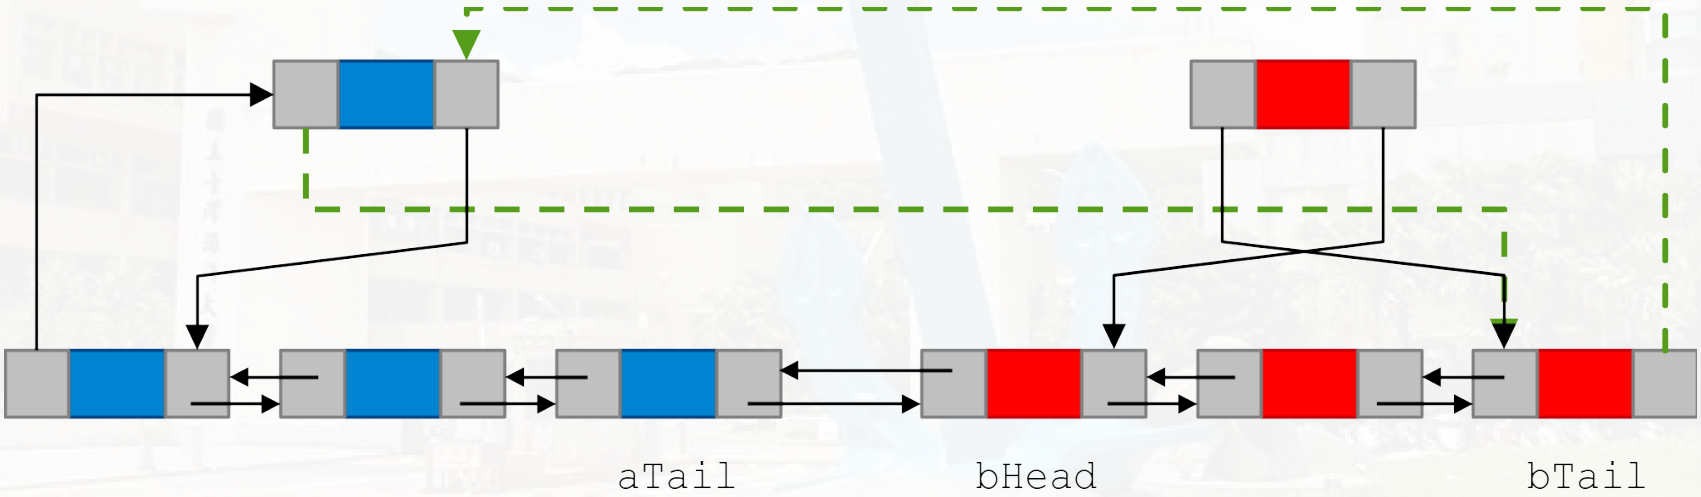
Concatenation of two doubly linked circular list



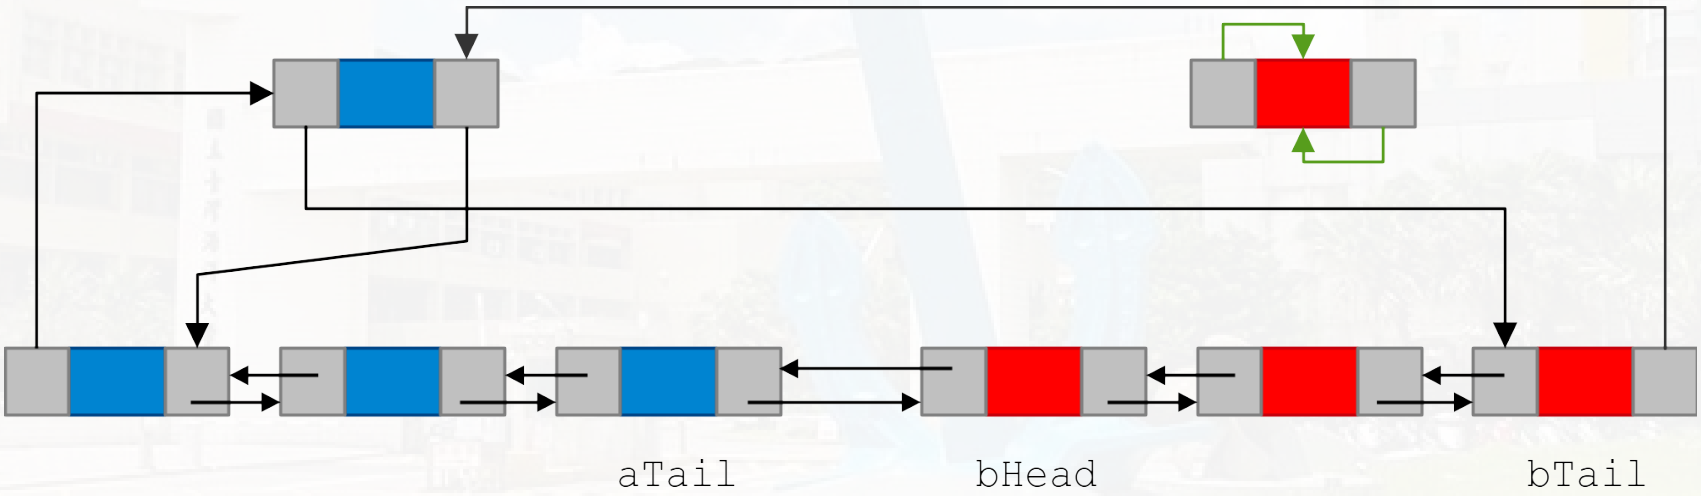
Concatenation of two doubly linked circular list



Concatenation of two doubly linked circular list



Concatenation of two doubly linked circular list



Concatenation of two doubly linked circular lists

```
void concat(Node *headerA, Node *headerB) {
    if (headerA == headerB) return;  /* avoid self-append */
    if (headerB->rlink == headerB) return; /* B is empty so skipped*/

    Node *aTail = headerA->llink;   // get the last node of A
    Node *bHead = headerB->rlink;   // get the first node of B
    Node *bTail = headerB->llink;   // get the last node of B

    // Stitch B after A's tail
    aTail->rlink = bHead;
    bHead->llink = aTail;

    // Close the ring back to headerA
    bTail->rlink = headerA;
    headerA->llink = bTail;

    // Make B empty
    headerB->rlink = headerB->llink = headerB;
}
```
